Python Summer Course

Course 2: Functions, Lists, Dictionaries & Classes

Théophile Gentilhomme

August 4, 2025

List

A **list** is an ordered, changeable collection of items, written with square brackets.

```
fruits = ["apple", "banana", "cherry"]
  empty = []
3 \text{ mixed} = [1, "yes", True]
```

Key Features:

- Ordered: items have positions (indexes)
- Mutable: you can change, add, or remove items
- Can contain any type, even mixed types

Accessing Elements & Slicing

```
→ Start Over

 Python Code
                                                                              ▶ Run Code
 fruits = ["apple", "banana", "cherry", "orange", "melon"]
  print(fruits[0])
3 print(fruits[-1])
            → Start Over
Python Code
                                                                              ▶ Run Code
1 print(fruits[1:3])  # From index 1 to 2 → ['banana', 'cherry']
2 print(fruits[:2])  # From start to index 1 → ['apple', 'banana']
3 print(fruits[2:])  # From index 2 to end → ['cherry', 'orange']
 Python Code

→ Start Over

                                                                              ▶ Run Code
1 print(fruits[::2])  # Every 2nd item → ['apple', 'cherry']
2 print(fruits[::-1]) # Reversed list → ['orange', 'cherry', 'banana', 'apple']
```

List Manipulation

Add & Remove

Looping Through Lists

Useful Functions

Indexing Reminder

List Comprehension

List comprehensions are a concise way to **create new lists** by transforming or filtering items. it is also more efficient than doing a for loop.

```
1 new_list = [expression for item in iterable]
```

Example: Squares of numbers

With Condition: Even numbers

With Transformation

Tuple

A **tuple** is an ordered, immutable collection of values, like a list, but you **can't change it**.

```
1 my_tuple = (1, 2, 3)
2 empty = ()
3 single = (5,) # Comma is required for single-item tuples
```

Key Features:

- Ordered: elements have a position
- Immutable: you can't add, remove, or change items
- Can contain mixed types: ("Alice", 30, True)
- Supports indexing and slicing like lists

Example

Set

A **set** is an unordered collection of **unique** items. It is great for removing duplicates and testing membership.

Properties:

- Sets are **unordered**: no indexing
- Only **immutable** items allowed (no lists/dicts inside sets)

Set Operations

Methods

```
Python Code ⊕ Start Over

1 a.add(6)
2 a.remove(1)
3 print(a)
```

What I can't put in a set

Dictionaries

A **dictionary** is a collection of key-value pairs, like a real-life lookup table.

```
Python Code
            → Start Over
                                                                                  ▶ Run Code
 1_{v} person = {
        "name": "Alice",
       "age": 30,
        "is_student": False
 4
 5
 6
    print (person["name"])
 8
    # Empy dictionary
    my_dict = {} # or dict()
11
    # Add an element
    my_dict["Counts"] = 0
14 print (my_dict)
```

- Keys must be unique and immutable (e.g. strings, numbers)
- Values can be any type
- Dictionaries are unordered before Python 3.7

Dictionary Comprehension

You can also add a condition:

```
Python Code ⊕ Start Over

1 evens = {x: x for x in range(10) if x % 2 == 0}

2 print (evens)
```

Common Operations

main

Important:

- dictionnary logic is the base of JSON format (see later)
- dictionnary are used a lot to provdie data samples (e.g. ML/DL)

Functions

Functions are reusable blocks of code that perform a specific task.

```
def function_name(parameters):
    """

Optional docstring describing what the function does.

"""

* code block
    # many compicated things using parameters
    return result
    # or does not return anything
```

Example

Function Parameters & Return Values

Functions can take inputs (zero, one or more) and return outputs.

Important:

- Parameters are local names inside functions
- Return ends the function and gives back a value
- Docstring helps explain the function's purpose, but is optional

Example:

Mutable vs Immutable Parameters

When passing values to functions, behavior depends on whether the object is mutable or immutable.

Immutable (e.g. int, str, tuple)

- A copy of the value is passed
- Changes inside the function don't affect the original

Mutable (e.g. list, dict, set)

- A reference to the object is passed
- Changes inside the function do affect the original

Functions Call Functions

Functions can be combined, one function can call another to build **modular and reusable** logic.

Example: Grading system

```
→ Start Over
 Python Code
                                                                                ▶ Run Code
 1 def calculate_average(scores):
        return sum(scores) / len(scores)
 4 def determine_grade (average):
 5 ,
        if average >= 90:
 6
            return "A"
        elif average >= 75:
            return "B"
        elif average >= 60:
            return "C"
10
11 ...
        else:
12
            return "F"
13
14 def grade student (scores):
15
        avg = calculate_average(scores)
16
        grade = determine_grade(avg)
17
        return f"Average: {avg:.1f}, Grade: {grade}"
18
19
     Example usage
20
           rrado etudont/[QQ
     main
```

Key Concepts

- Each function has a clear responsibility
- Complex logic is broken into smaller, reusable pieces
- You can use if, for, and return together

Other features (introduced later or in provided references):

- Default values
- Function as arguement
- Lambda functions

Classes and Objects

A **class** defines a blueprint for objects: t groups **data** and **behavior** together.

We will not go into much details here, but just give an overview for yu to understand objects and how to use them.

Create a Simple Class

Create and Use an Object (Instance)

```
Python Code ⊕ Start Over

1 my_dog = Dog() # Create an object
2 my_dog.bark() # Call a method
```

The object my_dog is an **instance** of the class Dog.

Class Initialization with __init__

The <u>__init__</u> method runs **when the object is created** and sets initial values of the attributes.

Example with Constructor

```
→ Start Over

Python Code
                                                                                ▶ Run Code
 1 v class Dog:
 2 ,
        def __init__(self, name, age):
            self.name = name
            self.age = age
 5
        def speak(self):
 6 ,
            print(f"{self.name} says: Woof!")
 8
   my\_dog = Dog("Rex", 4)
   my_dog.speak() # "Rex says: Woof!"
11 print (my_dog.age) # 4
```

Important: self refers to the **current object**: you must include it in all methods!

Adding Behavior with Methods

You can define your own methods to give objects useful **behaviors**.

If a class represents a **coffee machine**, the methods represent different programms to make different coffee.

But all the programms use the same internal attributes (e.g. coffee, water), or even internal functions (e.g. grind coffee, heat water)

Example with State Change

```
→ Start Over
Python Code
                                                                              ▶ Run Code
 1 class Counter:
 2 ,
        def init (self):
            self.value = 0
        # We use default value if not supplied
 6 ,
        def increment(self, inc = 1):
            self.value += 1
 8
        def reset(self):
            self.value = 0
10
11
    counter = Counter()
    counter.increment()
    counter.increment()
   print(counter.value) # 2
   counter.reset()
17 print (counter.value) # 0
```

Objects remember their state, and methods can modify it.

Your turn!

Define student data: Create a list of students. Each student is a dictionary containing:

- "name" (string),
- "age" (int),
- "grades" (a dictionary of course: grade pairs)

Solution

Show Solution

Enter code

Write functions, taking your list of students, to:

- Display all student names
- Calculate average grade for a given student (using building sum () function)

Solution

Show Solution

Enter code

Create a Student class

Define a class with attributes: name, age, grades, and methods to:

- Add a grade for a given course
- Compute the average for the student
- Display infos (whatever you want to print)

Solution

Enter code

Show Solution
